Accepted: September 2016

Food safety is still a worldwide concern so that, in many countries, production and distribution of safe and nutritious food is one of the most important problems; meanwhile, the right to have healthy food is obvious.

Recently food control systems have improved in many countries. However, while progress has been made, in 2010, the estimated global burden is reportedly about 600 million foodborne illnesses and 420,000 deaths (1). Application of new technologies for empowering detection and prevention of food born diseases is important to decline the burden of food-borne diseases (2); hence, empowerment of food safety system through developing the laboratory technologies from non-automated DNA sequencing methods to more rapid, automated sequencing methods such as whole genome sequencing (WGS) with the ability to sequence the entire genomes would have great impact on food safety management system.

WGS makes precise, rapid and helpful information to prevent food-borne diseases. In spite of the certain limitations in the field of technical and facilities infrastructures for implementation of this technology, performance and traceability of food safety management systems at national and international levels can be improved through application of whole genome sequencing in food, water, environmental and clinical samples continuously.

WGS is a new technology that can identify the complete DNA sequence of a food-borne pathogen genome. This laboratory methodology has an important role in improvement of food safety through making source tracking and traceability, source attribution, food system monitoring, disease surveillance, outbreak investigation, identification of

transmission pathways and monitoring food-borne diseases (3).

In addition, WGS is helpful in reducing food waste due to contamination, and thereby has a serious effect on food security. While WGS can properly contribute to improving food safety and security issues, lack of experienced experts for technical and bioinformatics purposes, providing necessary infrastructures for storage and data sharing facilities, and interpretation of laboratory data in epidemiological evidence are some barriers in globalization of this new method, and so its application remains relatively limited, especially in the developing and transitional countries (4). Due to the importance of technical aspects and infrastructures in implementation of WGS, decisions about when and where to use this technology for strengthening national food control systems need comprehensive assessment by each country (5, 6).

WGS has the potential to improve the performance of food safety management systems through food-borne diseases' surveillance, food tracing and monitoring, and detecting the source of contamination; in the meantime, there are some challenges in application of WGS to become a globally accepted methodology for identification of food-borne pathogens.
